# Low Cost Non-Dimming 220V Ballast Design 

## G EN ERAL D ESCRIPTIO N

This application note describes a high performance low cost ballast design using the ML4831 electronic ballast controller IC. The design can be evaluated by assembling the parts listed in this document.
Operating over the range of 198 to $242 \mathrm{~V}_{\text {RMS }}$ this power factor corrected 60 W electronic ballast is designed to power two series-connected F32T8 fluorescent lamps and displays all the features of Micro Linear's ML4831 ballast controller IC. The mode of operation used for preheating and striking of the lamps is the widely accepted variable frequency, non-overlapping inverter topology.
Figure 1 displays the block diagram of this 220 volt ballast design.

Figure 1
Applying AC line voltage to the ballast will supply start-up power to the ML4831 enabling gate drive for the PFC boost MOSFET Q1 and the inverter FETs Q2 \& Q3. PFC action generates a well regulated 380 VDC supply for the lamp inverter circuit and a low DC supply voltage for the ML4831. The inverter stage consists of 2 totem pole configured N -channel power MOSFETs with their common node supplying the lamp network. The pair of MOSFETs are driven out of phase by the ML4831 at a $50 \%$ duty cycle.
The lamp network is single low pass LC section which, when controlled from the ML4831, provides:

- Adjustable Lamp Power
- Required Lamp Starting Voltage
- Controllable Preheating Filament and Lamp Voltages
- Near Unity Power Factor
- High Input Impedance During Starting or Lamp-Out-of-Socket Conditions
- Less than 5\% Change in Lamp Current Over Line Voltage Operating Range
The series connected lamps are across the output of the network.

## LAM P N ETW O RK D ESIG N

The ML4831 allows the designer to select the filament preheating frequency and the lamp starting/minimum operating frequency.
The operation of the lamp network can be described by these equations:

Open Circuit (lamp starting) $e_{o}=\frac{\text { ein } x c}{x I+x c}$

During Lamp Operation $Q=\sqrt{\frac{r l}{\text { rin }}-1}$
Where:

| $\mathrm{e}_{\mathrm{IN}}$ | $=$ Equivalent RMS Network Input Voltage |
| :--- | :--- |
| $\mathrm{e}_{\mathrm{O}}$ | $=$ Open Circuit Network Output Voltage |
| VB | $=$ PFC Output Voltage |
| $\mathrm{x}_{\mathrm{C}}$ | $=$ Reactance of Shunt Capacitor |
| $\mathrm{x}_{\mathrm{L}}$ | $=$ Reactance of Series Inductor |
| Q | $=$ Transformation Q of network |
| $\mathrm{r}_{\mathrm{L}}$ | $=$ Equivalent Lamp Resistance at Po |
| $\mathrm{r}_{I N}$ | $=$ Transformed Value of $r_{\mathrm{L}}$ Needed to Produce $\mathrm{P}_{\mathrm{O}}$ |
| $\mathrm{P}_{\mathrm{O}}$ | $=$ Desired Lamp Power (Arc and Filament) |

High frequency measurements using reference lamps and ballast, as described in ANSI Standards C82.3-1983 and C78.375-1991, must be performed to determine lamp current and voltage at the desired ballast factor. These values are used to determine $P_{\mathrm{O}}$ and $\mathrm{r}_{\mathrm{L}}$.
Since the PFC uses a boost type converter:

$$
\begin{aligned}
& V B>\sqrt{ } \underline{2} \times V_{R M S} \text { line }(\max ) ; \\
& V B>(1.414)(1.1)(220), \text { and thus } \\
& V B>342 \mathrm{VDC}(380 \mathrm{VDC} \text { is used }) .
\end{aligned}
$$

The RMS amplitude of a square wave's fundamental is $\sqrt{2} / \pi$ times its peak-to-peak value.

## So,

$$
\mathrm{e}_{\mathrm{IN}}=0.45 \mathrm{VB}=171 \mathrm{~V}_{\mathrm{RMS}}
$$

And by assuming negligible losses in the reactances:

$$
\begin{align*}
& r_{I N}=\frac{e_{I N}^{2}}{P_{O}} \\
& =\frac{171^{2}}{55}=533 \Omega \tag{3}
\end{align*}
$$

## Application Note 52

From high frequency reference ballast measurements, F32T8 lamps operating at an 0.88 ballast factor,

$$
\begin{aligned}
& \text { Lamp Current }=0.18 \mathrm{~A}_{\text {RMS }} \\
& \text { Lamp Voltage }=136 \mathrm{~V}_{\text {RMS }} \\
& \text { Lamp Arc Power }=49 \text { watts (total) }
\end{aligned}
$$

$\mathrm{P}_{\mathrm{O}}$ (total) $=55$ watts (allocating 6 watts to filaments)
$r_{L}=1500 \Omega$ (total),
and from equation $2, \mathrm{Q}=1.35$
Values for $x_{C}$ and $x_{L}$ can be found from:

$$
\begin{equation*}
\mathrm{Q}=\frac{\mathrm{x}_{\mathrm{L}}}{\mathrm{r}_{\mathrm{N}}}=\frac{\mathrm{r}_{\mathrm{L}}}{\mathrm{x}_{\mathrm{C}}} \tag{4}
\end{equation*}
$$

Thus $x_{C}=-1113 \Omega$ and $x_{L}=718 \Omega$, and, from equation 1, $\mathrm{e}_{\mathrm{O}}=481 \mathrm{~V}_{\text {RMS }}$.

## CHOOSING THE STARTING/O PERATING FREQ UENCY

The operating frequency, $\mathrm{f}_{\mathrm{MIN}}$, was found by selecting a frequency that makes the shunt network capacitor a standard value using the values for $\mathrm{x}_{\mathrm{C}}$ and $\mathrm{x}_{\mathrm{L}}$ found in equation 4. A 4.7 nF capacitor makes $\mathrm{f}_{\text {MIN }} 30.5 \mathrm{kHz}$ and the inductor 3.75 mH .

For lamp rectification protection, line isolation, and lamp out detection 33 nF capacitors, C9 and C22, (see figure 5) were added in series with the inductor (T3 primary) on both the high and low sides of the line. The size of the inductor was increased to 5.4 mH to compensate for the added capacitance.

## Choosing the Preheating Frequency

The lamp starting scenario is the ballast feature that has the greatest impact on lamp life. The ML4831, when used with a properly designed lamp network, allows a designer to select:
a) The preheating frequency which sets voltage across the lamps and cathodes during the preheating interval
b) The length of the filament preheating time interval

ANSI C82.11-1993 sets the minimum preheating time at 0.5 seconds. A time of 0.7 seconds was used in this design with $265 V_{\text {RMS }}$ across the lamps. 260 volts was selected to ensure low glow current.
First select the voltage across the lamps during the preheating interval. Then use equation 1 to find the preheating frequency of 44 kHz . This should be above $\mathrm{f}_{\text {MIN }}$ to make the network inductive.

## Selecting $\mathbf{O}$ scillator Components

Inverter frequencies $f_{\text {MIN }}$ and $f_{\text {PREHT }}$, that were chosen to be 30.5 kHz and 44 kHz , respectively, are $1 / 2$ of the corresponding oscillator frequency. Refer to the ML4831 Data Sheet for the equations and device parameters to calculate $r_{T}$ and $r_{s}$. To get a discharge time near $1 \mu \mathrm{~s}$, the value for $\mathrm{C}_{\mathrm{T}}$ was chosen at 2.2 nF .

## NETW O RK IND UCTO R DESIG N

Since maximum stress on the inductor occurs during preheating, these conditions were used for its design. At fleEht $(44 \mathrm{kHz})$ :

$$
\begin{align*}
& \mathrm{x}_{\mathrm{L}}=1492 \Omega \\
& \mathrm{x}_{\mathrm{C}}=-772 \Omega \\
& \mathrm{e}_{\mathrm{O}}=265 \mathrm{~V}_{\mathrm{RMS}} \\
& \quad \mathrm{~V}_{\mathrm{IND}}=\left(\frac{265}{772}\right) 1492=513 \mathrm{~V}_{\mathrm{RMS}} \tag{5}
\end{align*}
$$

The E 25/7 (EF 25) core was selected because:

- Low Cost and Availability
- High Ae (core) X Aw (bobbin)
- Efficient size for 90VA at 30 kHz and 2000 gauss

For 2 turn filament windings at $4.5 \mathrm{~V}_{\text {RMS }}$ during preheating:

$$
\begin{equation*}
\frac{v}{t}=\frac{4.5}{2}=2.25 \tag{6}
\end{equation*}
$$

So the inductor turns are:

$$
\begin{equation*}
\mathrm{N}=\frac{513}{2.25}=228 \text { turns } \tag{7}
\end{equation*}
$$

Operating at an induction level of 2194 gauss during the lamp preheating interval.
Voltage across the inductor during normal lamp operation:

$$
\begin{align*}
& V_{I N D}=\left(x_{L}\right) \sqrt{\left(\frac{v_{L}}{r_{L}}\right)^{2}+\left(\frac{v_{L}}{x_{C}}\right)^{2}} \\
& =1034 \sqrt{\left(\frac{272}{1500}\right)^{2}+\left(\frac{272}{-1113}\right)^{2}}=315 \mathrm{~V}_{\mathrm{RMS}} \tag{8}
\end{align*}
$$

Where:

$$
\begin{array}{ll}
\mathrm{x}_{\mathrm{L}} & =\text { Reactance of } \mathrm{T} 3 \text { (primary) at } \mathrm{f}_{\mathrm{MIN}} \\
\mathrm{v}_{\mathrm{L}} & =\text { Voltage Across Lamps } \\
\mathrm{r}_{\mathrm{L}} & =\text { Total Equivalent Resistance of Lamps } \\
\mathrm{x}_{\mathrm{C}} & =\text { Reactance of C8 at } \mathrm{f}_{\mathrm{MIN}}
\end{array}
$$

The filament voltages during normal lamp operation:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{FIL}}=\frac{(315)(2)}{228}=2.76 \mathrm{~V}_{\mathrm{RMS}} \tag{9}
\end{equation*}
$$

## LAMP O PERATIO N

In equation 4 the entire load resistance is across the shunt capacitor. By taking the filament load, $r_{F}$, from a winding on the inductor, a resistance larger than the $\mathrm{r}_{I N}$ calculated in equation 3 is transformed which reduces the power available for the lamps. In this design, the filament power is small compared to the lamp arc power, so the mismatch is small. This effect can be mitigated by operating at a frequency slightly higher than $f_{\text {MIN }}$.
Network $Z_{I N}$ is found from the equation:

$$
\begin{equation*}
Z_{I N}=\left(r_{L S}+r_{F S}\right)+j\left(x_{L S}+x_{C S}\right) \tag{10}
\end{equation*}
$$

Where:

$$
\begin{aligned}
& \mathrm{r}_{\mathrm{LS}}=\text { Transformed Series Lamp Resistance } \\
& \mathrm{r}_{\mathrm{FS}}=\text { Transformed Series Filament Resistance } \\
& \mathrm{x}_{\mathrm{LS}}=\text { Transformed Series T3 (primary) reactance } \\
& \mathrm{x}_{\mathrm{CN}}=\text { Total Series Reactance of C9 and C22 } \\
& \mathrm{x}_{\mathrm{CS}}=\text { Transformed Series Capacitive Reactance } \\
& \text { of C8 }
\end{aligned}
$$

Expanded:

$$
\begin{align*}
& Z_{I N}=\left(\frac{r_{L}}{1+Q^{2}}+\frac{r_{F} \times n^{2}}{1+Q_{F}^{2}}\right)+j\left(\frac{x_{L} \times Q_{F}^{2}}{1+Q_{F}^{2}}+x_{C N}+\frac{x_{C} \times Q^{2}}{1+Q^{2}}\right)(11)  \tag{11}\\
& Q_{F}=\frac{r_{F} \times n^{2}}{x_{L}}  \tag{12}\\
& Q=\frac{r_{L}}{x_{C}} \text { and } n=\frac{\text { inductor turns }}{\text { filament turns }} \\
& =\left(\frac{1500}{1+1.35^{2}}+\frac{(2.5)\left(114^{2}\right)}{1+31^{2}}\right)+ \\
& j\left(\frac{(1034)\left(31^{2}\right)}{1+31^{2}}\right)-316+\frac{(-1113)\left(1.35^{2}\right)}{1+1.35^{2}}  \tag{13}\\
& \quad=531+34+j(1033-316-719)=565-j 2
\end{align*}
$$

As you can see from the results, the transformed filament resistance slightly reduced the power to the lamps.

$$
\begin{equation*}
\mathrm{P}_{\mathrm{O}}(\mathrm{new})=51.8 \text { watts } \tag{14}
\end{equation*}
$$

## LAMP OUT PRO TECTIO N

As with all resonant topology circuits, the highest component stress occurs at open load. This can be controlled by operating only close enough to resonance to produce adequate starting voltage. When we chose the starting voltage and derived $\mathrm{f}_{\mathrm{MIN}}$, the open circuit input impedance of the network was defined as:

$$
\begin{gather*}
Z_{I N}=r_{F S}+j\left(x_{L S}+x_{C N}+x_{C}\right) \\
=34+j(1033-316-1113)=-396 \Omega \tag{15}
\end{gather*}
$$

Where:

$$
\begin{aligned}
& \mathrm{r}_{\mathrm{FS}}=\text { Transformed Series Filament Resistance } \\
& \mathrm{x}_{\mathrm{LN}}=\text { Transformed Series Inductive Reactance } \\
& \mathrm{x}_{\mathrm{CN}}=\text { Reactance of Series Capacitors C9 and C22 } \\
& \mathrm{x}_{\mathrm{C}}=\text { Reactance of Shunt Capacitor, C8 }
\end{aligned}
$$

When operating at the resonant frequency of $40.4 \mathrm{kHz} \mathrm{Z}_{\mathrm{IN}}$ is $34 \Omega$ but by operating at $f_{\mathrm{MIN}}, Z_{\text {IN }}$ is $396 \Omega$ capacitive. Although $Z_{I N}$ is relatively high, switching losses would waste power and require additional heat sinking if not for the ML4831's duty cycle interruption feature.
The ML4831 uses duty cycle interruption of the inverter gate drive with the off time set by C13 and R15 (See figure 5). Refer to the ML4831 Data Sheet for information on value selection. Unloaded conditions are detected by sampling a voltage across C22, with a small capacitor. This voltage is then DC restored, rectified, filtered and applied to pin 9 of the ML4831. If a lamp is out of its socket, or does not ignite for any reason, the voltage across C22 will be more than $50 \%$ higher than when both lamps are operating and is high enough to activate the interrupt.

## Ballast Performance

A typical ballast of this design will have the following performance characteristics:

- Efficiency: 92\%
- Total Harmonic Distortion: 5\%
- Power Factor: 0.99
- Current Crest Factor: 1.3

## Application Note 52

## TYPICAL W AVEFO RMS

Figures 2 through 4 display typical oscilloscope waveforms taken at various points on the prototype. A brief description precedes each figure. Test conditions and oscilloscope settings are given below each photo. The waveforms were taken with the ballast powering two series connected F32T8 lamps.

## PFC BOOST VOLTAGE (FIG. 2)

The DC bus for the inverter stage is derived from the rectified AC line. Note the 120 Hz ( $2 x$ line frequency) ripple voltage superimposed on the DC voltage. This is the result of the power factor correction of the AC line voltage.

Figure 2. PFC Boost Voltage

## INVERTER VO LTAG E/CU RRENT (FIG. 3)

The boosted DC bus voltage is chopped by Q2 \& Q3, which causes a square wave to appear at the input to the lamp network (Q2/Q3/T3 node). The lamp network input current is sinusoidal due to the network Q . The current and voltage waveforms are in phase which indicates resonant operation and results in the minimum VA being supplied by the inverter to produce the required lamp watts.

Figure 3. Inverter O utput Voltage/Current

## LAMP CURRENT/VO LTAGE (FIG. 4)

A comparison of the lamp current and voltage is shown in Fig. 4. The small phase difference is typical when lamps are operated at high frequencies and is an indication of the increased lamp efficacy as compared to 60 HZ operation. The lamp current crest factor (CCF) is approx. 1.3, well below the 1.7 limit.

Figure 4. Lamp Current/Voltage
