# Application Note 42002 

ML4831 277 Volt Electronic Ballast Controller

## GENERAL DESCRIPTIO N

This application note describes a low cost dimmable ballast design using the ML4831 electronic ballast controller IC．The design can be evaluated by assembling the parts listed in this document．This design is a version of Micro Linear＇s ML4831 220V ballast EVAL board．The ML4831EVAL－220V is designed to be modified for 277 V operation by following the recommended changes in the parts list．
Operating over the range of 249 to $305 \mathrm{~V}_{\mathrm{RMS}}$ ，this power factor corrected 60 W electronic ballast，with a dimming range capable of a 10：1 intensity change，was optimized to power two series－connected F32T8 fluorescent lamps， and displays all the features of Micro Linear＇s ML4831 ballast controller IC．The mode of operation used for pre－ heat，striking and dimming of the lamps is the widely accepted variable frequency，non－overlapping inverter topology．
Figure 1 displays the block diagram of this 277 V ballast design．

Figure 1
Applying AC line voltage to the ballast will supply start－up power to the ML4831 enabling gate drive for the PFC boost MOSFET Q1 and the inverter FETs Q2 \＆Q3．PFC action generates a well regulated 450 VDC supply for the lamp inverter circuit and a low DC supply voltage for the ML4831．The inverter stage consists of 2 totem pole configured N －channel power MOSFETs with their common node supplying the lamp network．The pair of MOSFETs are driven out of phase by the ML4831 at a $50 \%$ duty cycle．

The lamp network is single low pass LC section which when controlled from the ML4831 provides：
－Adjustable lamp power
－Required lamp starting voltage
－Controllable preheating filament and lamp voltages
－Near unity power factor
－High input impedance during starting or lamp－out－of－ socket conditions
－Linear dimming with filament voltages increasing as lamp current is decreased
The series connected lamps are across the output of the LC network．

## LAMP NETW ORK DESIGN

The ML4831 allows the designer to select the filament preheating frequency and the lamp starting／minimum operating frequency．
The operation of the lamp network can be described by equations：

$$
\begin{equation*}
\mathrm{e}_{\mathrm{O}}=\frac{\left(\mathrm{e}_{I N}\right)\left(\mathrm{x}_{\mathrm{C}}\right)}{\mathrm{x}_{\mathrm{L}}+\mathrm{x}_{\mathrm{C}}} \tag{1}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{Q}=\sqrt{\frac{r_{\mathrm{L}}}{r_{\mathrm{IN}}}-1} \tag{2}
\end{equation*}
$$

Where：

$$
\begin{aligned}
& \mathrm{e}_{\mathrm{IN}}=\text { equivalent RMS network input voltage } \\
& \mathrm{e}_{\mathrm{O}}=\text { Open circuit network output voltage } \\
& \mathrm{VB}=\text { PFC output voltage } \\
& \mathrm{x}_{\mathrm{C}}=\text { Reactance of shunt capacitor } \\
& \mathrm{x}_{\mathrm{L}}=\text { Reactance of series inductor } \\
& \mathrm{Q}=\text { Transformation } \mathrm{Q} \text { of network } \\
& \mathrm{r}_{\mathrm{L}}=\text { Equivalent lamp resistance at } \mathrm{P}_{\mathrm{O}} \\
& \mathrm{r}_{\mathrm{IN}}=\text { Transformed value of } \mathrm{r}_{\mathrm{L}} \text { needed to produce } \mathrm{P}_{\mathrm{O}} \\
& \mathrm{P}_{\mathrm{O}}=\text { Desired lamp power (arc and filament) }
\end{aligned}
$$

## Application N ote 51

High frequency measurements using reference lamps and ballasts as described in ANSI Standards C82.3-1983 and C78.375-1991, must be performed to determine lamp current and voltage at the desired ballast factor. These values are used to determine $P_{O}$ and $r_{L}$.
Since the PFC uses a boost type converter:
$\mathrm{VB}>\sqrt{2} \times \mathrm{V}_{\mathrm{RMS}}$ line (max);
$\mathrm{VB}>(1.414)(1.1)(277)$, and thus
$\mathrm{VB}>431 \mathrm{VDC}(450 \mathrm{VDC}$ is used).

The RMS amplitude of a square wave's fundamental is $\sqrt{2} / \pi$ times its peak to peak value.

So;

$$
\mathrm{e}_{\mathrm{IN}}=0.45 \mathrm{VB}=203 \mathrm{~V}_{\mathrm{RMS}}
$$

And by assuming negligible losses in the reactances;

$$
\begin{align*}
& r_{\mathrm{IN}}=\frac{\mathrm{e}_{\mathrm{IN}}}{\mathrm{P}_{\mathrm{O}}} \\
& =\frac{203^{2}}{54}=761 \Omega \tag{3}
\end{align*}
$$

From high frequency reference ballast measurements, F32T8 lamps operating at an 0.86 ballast factor;

$$
\begin{aligned}
& \text { lamp current }=0.175 \mathrm{~A}_{\mathrm{RMS}} \\
& \text { lamp voltage }=140 \mathrm{~V}_{\mathrm{RMS}} \\
& \text { lamp arc power }=49 \mathrm{~W} \text { (total) } \\
& \mathrm{P}_{\mathrm{O}}(\text { total })=54 \mathrm{~W} \text { (allocating } 5 \mathrm{~W} \text { to filaments) } \\
& \mathrm{r}_{\mathrm{L}}=1600 \Omega \text { (total), } \\
& \text { and, from equation }(2), \mathrm{Q}=0.986 .
\end{aligned}
$$

Values for $x_{C}$ and $x_{L}$ can be found from:

$$
\begin{equation*}
\mathrm{Q}=\frac{\mathrm{x}_{\mathrm{L}}}{r_{\mathrm{IN}}}=\frac{\mathrm{r}_{\mathrm{L}}}{\mathrm{x}_{\mathrm{C}}} \tag{4}
\end{equation*}
$$

Thus $\mathrm{x}_{\mathrm{C}}=-1522 \Omega$ and $\mathrm{x}_{\mathrm{L}}=750 \Omega$, and, from equation (1), $\mathrm{e}_{\mathrm{O}}=400 \mathrm{~V}_{\mathrm{RMS}}$.
In this case there is insufficient voltage to reliably start the two lamps. A minimum starting voltage of $480 \mathrm{~V}_{\text {RMS }}$ is required. Providing more starting voltage usually will require that a transformer be included in the network design. However, since the network nearly produces enough voltage, choosing a operating frequency ( $\mathrm{f}_{\mathrm{MIN}}$ ), which is slightly higher than the unity power factor (resonant) frequency (f: ${ }_{\text {DES }}$ ), can provide the additional starting voltage.

## CHOOSING THE STARTING / O PERATIN G FREQU ENCY

The operating frequency, $f_{\text {MIN }}$, was found by:
a) finding a frequency - $f_{\text {DES }}$ - to make the shunt network capacitor a standard value using the resonant values for $\mathrm{x}_{\mathrm{C}}$ and $\mathrm{x}_{\mathrm{L}}$ of $-1522 \Omega$ and $750 \Omega$, respectively. Using a 3.3 nF capacitor makes $\mathrm{f}_{\mathrm{DES}}=30.8 \mathrm{kHz}$ and the inductor 3.88 mH .
b) choosing a starting voltage, $\mathrm{e}_{\mathrm{O}}(507 \mathrm{~V})$, then using equation 1 ) to find $f_{\text {MIN }}$ from the capacitance and inductance values found in paragraph a).

$$
\mathrm{f}_{\mathrm{MIN}}=34 \mathrm{kHz}
$$

For lamp rectification protection, line isolation, and Q enhancement, 33 nF capacitors C9 and C22 (see figure 10) were added in series with the inductor on both the high and low sides of the line. The size of the inductor was increased to 5.5 mH to compensate for the added capacitance. Since this increased the network $Q$ at $f_{M I N}$, the starting voltage increased to $567 \mathrm{~V}_{\text {RMS }}$. $\mathrm{F}_{\text {MIN }}$ can be reduced to 33.15 kHz to keep the starting voltage at $507 \mathrm{~V}_{\text {RMS }}$.

## CHOOSING THE PREH EATING FREQ U EN CY

The lamp starting scenario is the ballast characteristic that has the greatest impact on lamp life. The ML4831, when used with a properly designed lamp network, allows a designer to select:
a) the filament preheating time interval, and
b) the voltage across the lamps and filaments during the preheating interval.

ANSI C82.11-1993 sets the minimum preheat time at 0.5 seconds. A time of 0.7 seconds was used in this design with $290 V_{\text {RMS }}$ across the lamps, and filament voltages of $6.0 \mathrm{~V}_{\text {RMS }}$ during preheating. This gives a good hot to cold filament resistance ratio, $R_{H} / R_{C}$, and low glow current. Equation (1) is used to find the preheat frequency of 51 kHz using 290 V for $\mathrm{e}_{\mathrm{O}}$.

## SELECTING O SCILLATOR COMPONENTS

Inverter frequencies $f_{\text {MIN }}$ and $f_{\text {PREHT }}$ that were chosen to be 33 kHz and 51 kHz , respectively, are $1 / 2$ of the corresponding oscillator frequency. Refer to the ML4831 Data Sheet for the equations and device parameters to calculate $r_{T}$ and $r_{S}$. To get a discharge time near $1 \mu \mathrm{~s}$ the value for $\mathrm{C}_{\mathrm{T}}$ was chosen at 2.2 nF .

## NETWO RK INDUCTO R DESIGN

Since maximum stress on the inductor occurs during preheating, those conditions were used for its design. At frREHT:

$$
\begin{aligned}
& \mathrm{x}_{\mathrm{L}}=1760 \Omega \\
& \mathrm{x}_{\mathrm{C}}=-919 \Omega \\
& \mathrm{e}_{\mathrm{O}}=290 \mathrm{~V}_{\mathrm{RMS}}
\end{aligned}
$$

$$
\begin{align*}
\mathrm{V}_{\text {IND }} & =\left(\frac{290}{919}\right) 1760  \tag{5}\\
& =555 \mathrm{~V}_{\text {RMS }}
\end{align*}
$$

The E 25/7 (EF 25) core was selected because:

- low cost and availability
- high $\mathrm{A}_{\mathrm{E}}$ (core) X $\mathrm{A}_{\mathrm{W}}$ (bobbin)
- efficient size for 90VA at 30 kHz and 2000 gauss

For 2 turn filament windings at $6 \mathrm{~V}_{\mathrm{RMS}}$ during preheating;

$$
\begin{equation*}
\mathrm{N}=\frac{555}{3}=185 \text { turns } \tag{6}
\end{equation*}
$$

Operating at a induction level of 2523 gauss during the lamp preheating interval.

Voltage across the inductor during normal lamp operation;

$$
\begin{align*}
& V_{I N D}=\left(X_{L}\right) \sqrt{\left(\frac{V_{L}}{r_{L}}\right)^{2}+\left(\frac{V_{L}}{x_{C}}\right)^{2}} \\
& =1174 \sqrt{\left(\frac{280}{1600}\right)^{2}+\left(\frac{280}{-1379}\right)^{2}}=315 \mathrm{~V}_{\mathrm{RMS}} \tag{7}
\end{align*}
$$

Where;
$x_{L}=$ reactance of series network inductor (T3) at $f_{\text {MIN }}$
$\mathrm{V}_{\mathrm{L}}=$ voltage across lamps
$\mathrm{x}_{\mathrm{C}}=$ reactance of shunt capacitor (C8)
The filament voltages during normal lamp operation;

$$
\begin{equation*}
\mathrm{V}_{\mathrm{FIL}}=\frac{(315)(2)}{185}=3.4 \mathrm{~V}_{\mathrm{RMS}} \tag{8}
\end{equation*}
$$

## LAMP O PERATIO N

The effect of the power delivered to the filaments ( $r_{F}=$ $2.5 \Omega$ total) must be considered in the determination of arc power and lamp current. If the network is operated at $f_{\mathrm{DES}}$ ( 30.8 kHz ) the transfromed series inductance, $\mathrm{x}_{\mathrm{L}}$ in equation 4), is slightly reduced due to the reflected filament resistance; however, the addition of the transformed series filament resistance to the transformed series lamp resistance results in a total resistance of $815 \Omega$. This is larger than $r_{I N}(761 \Omega)$ thereby reducing the power delivered to the lamps. By operating at $\mathrm{f}_{\mathrm{MIN}}(34 \mathrm{kHz})$, the total series resistance is reduced to $749 \Omega$ with a $Z_{I N}$ of $755 \Omega$. So by operating slightly above the design frequency more starting voltage and power can be supplied to the lamps at a power factor near unity. $\mathrm{Z}_{\text {IN }}$ is found from the equation:

$$
\begin{equation*}
Z_{I N}=\left(r_{L S}+r_{F S}\right)+j\left(x_{L S}+x_{C N}+x_{C S}\right) \tag{9}
\end{equation*}
$$

Where:
$r_{\mathrm{LS}}=$ transformed series lamp resistance;
And;
$r_{\mathrm{FS}}=$ transformed series filament resistance;
$x_{\text {LS }}=$ transformed series inductive reactance; and
$x_{C S}=$ transformed series capacitive reactance (C8)
$\mathrm{x}_{\mathrm{CN}}=$ total series reactance of C 9 and C 22
Expanded:
$Z_{I N}=\left(\frac{r_{L}}{1+Q^{2}}+\frac{\left(r_{F}\right)\left(n^{2}\right)}{1+Q_{F}^{2}}\right)+j\left(\frac{\left(x_{L}\right)\left(Q_{F}^{2}\right)}{1+Q_{F}{ }^{2}}+x_{C N}+\frac{\left(x_{C}\right)\left(Q^{2}\right)}{1+Q^{2}}\right)$
Where $\quad \mathrm{n}=\frac{\text { inductor turns }}{\text { filament turns }}=\frac{185}{2}=92.5$

$$
\begin{gathered}
Q=\frac{r_{L}}{x_{C}}=1.16 \\
Q_{F}=\frac{\left(r_{F}\right)\left(n^{2}\right)}{x_{L}}=\frac{(2.5)\left(92.5^{2}\right)}{1174}=18.2 \\
=\left(\frac{1600}{1+1.16^{2}}+\frac{(2.5)\left(92.5^{2}\right)}{1+18.2^{2}}\right)+ \\
j\left(\frac{(1174)\left(18.2^{2}\right)}{1+18.2^{2}}-284+\frac{(-1379)\left(1.16^{2}\right)}{1+1.16^{2}}\right) \\
Z_{\text {IN }}=(682+64)+j(1170-284-791)=746+j 95=752 \Omega \\
\text { So, } \quad P_{\mathrm{O}}(n e w)=54 \text { watts }
\end{gathered}
$$

By operating slightly higher than the resonant frequency, $f_{\text {DES }}$, we obtained the desired starting voltage and power to the lamps with a small inductive phase angle of 7 degrees.

## LAMP O U T PROTECTIO N

As with all resonant topology circuits, the highest component stress occurs at open load. This can be controlled by operating only close enough to resonance to produce adequate starting voltage. When we chose the starting voltage and derived $\mathrm{f}_{\mathrm{MIN}}$, the open circuit input impedance of the network was defined:

$$
\begin{gather*}
Z_{I N}=r f s+j(x \ln +x c n+x c) \\
=67+j(1170-284-1379)=497 \Omega \tag{11}
\end{gather*}
$$

Where:

$$
\begin{aligned}
& \mathrm{r}_{\mathrm{FS}}=\text { transformed series filament resistance; } \\
& \mathrm{x}_{\mathrm{LN}}=\text { transformed series inductive reactance; } \\
& \mathrm{x}_{\mathrm{CN}}=\text { reactance of series capacitors } \mathrm{C} 9 \text { and } \mathrm{C} 22 ; \text { and } \\
& \mathrm{x}_{\mathrm{C}}=\text { reactance of shunt capacitor, } \mathrm{C} 8 .
\end{aligned}
$$

## Application Note 51

At the resonant frequency of $40.4 \mathrm{kHz}, \mathrm{Z}_{\mathrm{IN}}$ is $67 \Omega$.
Operating at $f_{M I N}, Z_{\text {IN }}$ is $497 \Omega$ capacitive. Although $Z_{\text {IN }}$ is relatively high, switching losses would waste power and require additional heat sinking if not for the ML4831's duty cycle interruption feature.
The ML4831 uses duty cycle interruption of the inverter gate drive with the off time set by C13 and R15 (See figure 10). Refer to the ML4831 Data Sheet for information on value selection. Unloaded conditions are detected by comparing a voltage created by the sampled lamp current at pin 2 of the 393 dual comparator with a reference voltage. If, at the end of the lamp starting scenario, lamp current is not detected the interrupt circuit is activated. The other comparator output, pin 7, activates the lamp feedback amplifier when lamp current is detected.

## DIMMING

The light output of a fluorescent lamp is very closely related to both lamp current and arc watts. Light output is controlled by sampling the lamp current with current sensing transformer T5. Its secondary current is converted to a voltage and fed to the ML4831's Lamp Feedback Amplifier. The Amplifier output voltage varies in accordance with the amount of lamp current required (set by potentiometer R20) by internally adjusting the inverter frequency. The impedance characteristic of the lamp network results in lower lamp current (light) as the inverter frequency is increased.
If dimming is not desired:
T5, IC2, D8, D11, D16, R2, R3, R16, R20, R22, R24, R26, R27, R28, R29 C4 and C21 can be removed. Lamp out protection can be reinstated by sampling the voltage across C22 with a small capacitor. This voltage can then be DC restored, rectified, filtered and applied to pin 9 (2 diodes, 2 capacitors and 2 resistors). A good interrupt signal can be obtained since the voltage across C22 is more than $50 \%$ higher with a lamp out. See Application Note 52. Pin 5 must be grounded.

## PERFO RMANCE DATA

To measure system performance across the range of permissible input voltages use a variable or adjustable AC source.
A typical ballast of this design will have the following performance characteristics when operated as shown in the test conditions:

## BALLAST TEST RESU LTS

| INPUT | $\mathbf{2 4 9}$ | $\mathbf{2 7 7}$ | $\mathbf{3 0 5}$ | VOLTS |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{P}_{\text {IN }}$ | 58.8 | 58.8 | 58.6 | Watts |
| THD | 5.0 | 5.3 | 7.8 | $\%$ |
| PF | 0.99 | 0.99 | 0.99 |  |
| OUTPUT |  |  |  |  |
| Lamp I |  |  |  |  |
| CCFS | 0.168 | 0.169 | 0.170 | $\mathrm{~A}_{\text {RMS }}$ |
| $\mathrm{V}_{\text {FIL }}$ | 1.26 | 1.25 | 1.27 |  |

Test Conditions: 2 series wired T8 lamps (full intensity); $22^{\circ} \mathrm{C}$
Equipment Used: Voltech Digital AC Power Analyzer \#PM1000
Tektronix TDS 460 Digitizing Scope; Fluke 8920A; Tektronix 6021 current probe.

Test points are provided at the following circuit nodes:

| TP1 | Circuit GND |
| :--- | :--- |
| TP2 | $V_{\text {CC }}$ |
| TP3 | Interrupt |
| TP4 | PFC Boost Voltage |
| TP5 | Output |

## Application Note 51

## TYPICAL WAVEFO RMS

Figures 2 through 4 display typical oscilloscope waveforms taken at various points on the EVAL Board. A brief description precedes each figure. Test conditions and oscilloscope settings are given below each photo. The waveforms were taken with the ballast powering two series connected F32T8 lamps.

## PFC BOOSTVOLTAGE (FIG. 2,TP4)

The DC bus for the inverter stage is derived from the rectified AC line. Note the 120 Hz ( $2 x$ line frequency) ripple voltage superimposed on the DC voltage. This is the result of the power factor correction of the AC line voltage. The peak to peak amplitude of the ripple voltage increases as the lamp intensity increases.

Figure 2. PFC BoostVoltage
Scope Setting: Vert. $=100 \mathrm{~V} / \mathrm{div}$. , Horiz. $=10 \mathrm{~ms} /$ div.
Test Conditions: Lamps @ maximum intensity, 277VAC
Equipment Used: Tektronix TDS540 Digitizing Scope

## INVERTER VO LTAG E/CU RRENT (FIG. 3)

The boosted DC bus voltage is chopped by Q2 \& Q3 resulting in the square wave appearing at the input to the lamp network (Q2/Q3/T4 node). The lamp network input current is sinusoidal due to the network Q. The current and voltage waveforms are nearly in phase which results in the minimum VA being supplied by the inverter to produce the required lamp watts. The small inductive phase ensures low switching losses.

Figure 3. Inverter O utput Voltage/Current
Scope Setting: Ch4-200mA/div, Ch1-100V/div, Horiz $=10 \mu \mathrm{~s} / \mathrm{div}$
Test Conditions: Lamps @ maximum intensity, 277VAC
Equipment Used: Tektronix TDS540 Digitizing Scope, Tektronix 6021
Current Probe

## LAMP CURRENT/VO LTAGE (FIG. 4)

A comparison of the lamp current and voltage is shown in Fig. 4. The small phase difference is typical when lamps are operated at high frequencies and is an indication of the increased lamp efficacy as compared to 60 Hz operation. The lamp current crest factor (CCF) is approx. 1.3 , well below the 1.7 limit. The user will note an increase in lamp voltage as the lamp is dimmed. This is a result of the negative resistance characteristic of a fluorescent lamp.

Figure 4. Lamp Current/Voltage
Scope Setting: Ch3 $=200 \mathrm{~V} / \mathrm{div}, \mathrm{Ch} 4=0.1 \mathrm{~A} / \mathrm{div}$, Horiz. $=10 \mu \mathrm{~s} / \mathrm{div}$
Test Conditions: Lamps @ maximum intensity, 277 VAC
Equipement Used: Tektronix TDS540 Digitizing Scope, Tektronix 6021 Current Probe

Note: Shading denotes those items that must be changed on the ML4831EVAL board for 277 volt operation.

## Application Note 51

## 277 VO LT ML4831 PARTS LIST (continued)

| Item | Q ty | D escription | Designation |
| :---: | :---: | :---: | :---: |
| Transformers |  |  |  |
| 55 | 1 | Boost inductor: 5.0 mH , Premier Magnetics P/N <br> TSD-746; or EF25 core set, Seimens P/N B66317-G-X127, 10 pin vertical bobbin Seimens P/N B66208-J1110-T001. Wind as follows: 240 turns 27 AWG magnet wire - start pin 7, end pin 10; 1 layer mylar tape; 18 turns 30 AWG magnet wire-start pin 8 , end pin 9. <br> Note: Gap for $5.0 \mathrm{mH} \pm 3 \%$. ( $\mathrm{Al}=87 \pm 3 \%$ ) pins 7 to 10 . | T1 |
| 56 | 1 | Gate drive transformer, Lpri $=16 \mathrm{mH}(\mathrm{min})$ : <br> Premier Magnetics P/N TSD-747; core Magnetics, Inc. P/N ZW-41407-TC; or Lodestone Pacific toroid mount P/N TM550-8. Wind as follows: 60 turns 36 AWG trifilar quadruple build magnet wire (red, green and clear). Connect flying leads as follows: red (start) pin 6, red (end) pin 7; green (start) pin 2, green (end) pin 3; clear (start) pin 1, clear (end) pin 8. | T2 |
|  |  | Not used Assembly note: Install jumpers from pin 10 to pin 4 and from pin 5 to pin 6. | T3 |
| 57 | 1 | Inductor, Lpri $=5.5 \mathrm{mH}$ : Premier Magnetics P/N TSD-780; or EF25 core set, or Seimens P/N B66317-G-X127; 10 pin vertical bobbin Seimens P/N B66208-J1110-T001. Wind as follows: 181 turns 28 AWG QPN magnet wire-start pin 6, end pin 7; 1 layer mylar tape; 2 turns 28 AWG QPN magnet wire - start pin 2, end pin 1; 2 turns 28 AWG QPN magnet wire-start pin 4, end pin 3; 2 turns 28 AWG QPN magnet wirestart pin 8 , end pin 9; Note: Gap for $5.5 \mathrm{mH} \pm 3 \%$. ( $\mathrm{Al}=76 \pm 3 \%$ ) pins 6 to 7 . | T4 |
| 58 | 1 | Current sense inductor: Premier Magnetics P/N TSD-749; or core Magnetics, Inc. P/N ZW-41407-TC (or equiv.); Lodestone Pacific toroid mount P/N TM550-6. Wind as follows: Primary = 4 turns 30 AWG kynar wire - start pin 1, end pin 5; Secondary $=400$ turns 32 AWG magnet wire - start pin 10, end pin 6. | T5 |

## DISCLAIMER

FAIRCHILD SEMICONDUCTOR RESERVES THE RIGHT TO MAKE CHANGES WITHOUT FURTHER NOTICE TO ANY PRODUCTS HEREIN TO IMPROVE RELIABILITY, FUNCTION OR DESIGN. FAIRCHILD DOES NOT ASSUME ANY LIABILITY ARISING OUT OF THE APPLICATION OR USE OF ANY PRODUCT OR CIRCUIT DESCRIBED HEREIN; NEITHER DOES IT CONVEY ANY LICENSE UNDER ITS PATENT RIGHTS, NOR THE RIGHTS OF OTHERS.

## LIFE SUPPORT POLICY

FAIRCHILD'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF FAIRCHILD SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user.
2. A critical component in any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

[^0]:    Note: Shading denotes those items that must be changed on the ML4831EVAL board for 277 volt operation.
